

POST OPERATIVE CARE FOR BROW LIFT

Eyebrow and forehead lifting is performed by cutting across the skin above the brow, resulting in a long scar within the brow hairline, along a forehead furrow, or behind the hairline to camouflage the scar. Another effective method requires an incision site and scar across the scalp from ear to ear. Such incisions can still be useful in some situations, but we are able to offer many patients an endo-brow lift which is far less invasive eyebrow and forehead lift. With this procedure Dr. Jose Barrera will use a small camera and specialized instruments to make tiny incisions behind the hairline to carefully lift the brow.

For most patient's recovery time is brief and bruising is minimal.

Other procedures may be performed with an endo-brow lift, including laser resurfacing for facial wrinkles and skin tightening, eyelid lift, facelift, facial fat transfer, and rhinoplasty. This advanced skin resurfacing technology offers numerous advantages over conventional techniques, including:

- Extremely precise control and advanced capabilities
- Lower risk of unpleasant recovery issues
- Typical recovery time after only 4-7 days
- Convenient facilities in our outpatient surgery center
- Integration of multiple procedures as part of a personalized facial surgery plan

Your doctor will tailor his approach to give you the most extraordinary results for you.

The main risks of eyelid/eyebrow surgery are rare and include bleeding causing vision loss (extremely rare), infection, asymmetry, scarring, over and under-correction, need for more surgery, and dry eyes.
